(54) Title: SUCTION DEVICE WITH MEANS FOR REMOVING A REPLACEABLE TIP**(57) Abstract**

The object of the invention is a method for removing a replaceable tip (2) used with a suction device for dispensing a liquid, wherein the tip (2) is removed by bringing a removal means (4), arranged in an air space formed jointly by a sample space of a replaceable tip and a cylindrical space (8) of an end part (1) of a suction device, movable between its two extreme positions, namely an inner home position (6b) and an outer removal position (6c), into cooperation with an inside surface of the replaceable tip (2) mounted on the end part (1), whereby the movement of the removal means (4) into its removal position (6c) causes the replaceable tip (2) to be detached from the end part (1). The object of the invention is also a suction device for using the method according to the invention.

SUCTION DEVICE WITH MEANS FOR REMOVING A REPLACEABLE TIP

The object of this invention is a method for removing a replaceable tip for use in a suction device for dispensing, transferring, diluting, titrating, or mixing a liquid,
5 or for a combination of all or some of these operations.

The object of this invention is also a suction device for dispensing, transferring, diluting, titrating or mixing a liquid, or for a combination of all or some of these operations, which suction device has an end part enclosing a cylindrical space
10 having a reciprocating piston for changing the volume of the cylindrical space, the end part being provided with an aperture in the extremity thereof intended for receiving a replaceable tip, in order to form a gas passage between the sample space of the said replaceable tip and the cylindrical space, and which has means for removing the tip.

15

Since the 1970s suction devices have been in use, in which the replaceable tip has been released and removed from the body with mechanical means without the need to touch the replaceable tip by hand. This is to avoid getting into contact with active and often even dangerous chemical and biological samples and
20 reagents. The solutions have included mechanisms comprising levers or sleeves which have been mounted upon the pipette body. These mechanisms, which are known among others from the Finnish patent publications 56937 and 57540, have, however, increased the outer dimensions of the body beyond the outer diameter of the replaceable tip. From the US-patent 4,616,514 a suction device is known in
25 which the replaceable tip is attached to the body the end part having finger-like strips provided with shoulders and in which the replaceable tip is released with a moveable means mounted within the end part acting on the finger-like strips. Also in this solution the end part will be greater than the replaceable tip to its diameter. In the development of diagnostic methods, nowadays one strives at such methods,
30 in which the volumes of the samples and reagents utilized are increasingly smaller, which also leads to the use of increasingly smaller sample tubes. The removal means for replaceable tips mounted on the body of the suction device have restrained the changeover to using small sample tubes and therefore the

removal devices have been removed from the suction devices. In these cases the tips have to be removed manually, whereby the risk for contamination again increases. There are also procedures in use in which the replaceable tip is removed by means of a U-shaped notch located in the side of a waste container.

5

In the following, the 'suction device' stands for as such known manual or electrical suction devices or pipettes, which are used for pipetting, dispensing, diluting, titrating or mixing, or for a combination of all or some of these operations.

10

The use of these suction devices in handling liquids, such as samples or reagents, is described as a simplified example in the following. Once a replaceable tip has been attached to the end part of the body of the suction device and the piston moving in the cylindrical space of the end part is brought to its home position, whereby the piston is situated in the cylindrical space at that end which is closest

15

to the end part of the suction device, the handling can be started. The outermost open end of the replaceable tip is immersed into the liquid of which it is desired to take a sample. When the piston is now moved inwards into the cylindrical space, the change in the volume formed jointly by the sample space of the replaceable tip and the cylindrical space brings about suction of the sample or

20

reagent into the sample space of the replaceable tip. When it is desired to dispense the sample or the reagent taken in this way into the tip, the piston is moved towards the end part, whereby the said volume diminishes and at the same time the liquid in the replaceable tip exits from the open end of the replaceable tip.

25

Several of these suction and dispensing stages can be combined in succession to bring about the desired handling. In these stages of sample handling the piston is moved to bring about the desired suction or dispensing. In most cases as the last stage the piston is moved past its home position mentioned above to a blowout position so that the replaceable tip is completely emptied. Thereafter the replaceable tip is removed from the end part of the body of the suction device.

30

The object of the invention is to provide a method and a device using the same for removing tips used in suction devices without touching them manually. It is

essential for this invention that the means needed for the removal are at least mainly within the body of the suction device and do not thereby increase the outer dimensions of the end part of the suction device beyond the outer diameter of the replaceable tip.

5

The method being the object of the invention is characterized in that the replaceable tip is removed by bringing a removal means, mounted in the air space formed jointly by the sample space of the replaceable tip and the cylindrical space of the end part of the suction device, which is movable between its two extreme positions, namely an inner home position and an outer removal position, to move into cooperation with an inside surface of the replaceable tip mounted on the end part, whereby the movement of the removal means into its removal position brings about the detachment of the replaceable tip from the end part.

15 Bringing the removal means into cooperation with the inside surface of the tip means that the movement of the removal means is communicated to cause a removal movement of the replaceable tip attached to the end part of the body of the suction device, e.g. by bringing the removal means in contact with the inside surface of the replaceable tip, or in contact with means associated with the inside surface of the tip, such as projections, pegs, ribs, fins, circular projections, or with means within the said air space engaging the inside surface of the tip.

25 The removal of the tip in the method according to the invention can take place so that the removal means in moving to the position for removal, extends outside through an aperture in the end part into the sample space of the tip into contact with the inside surface of the tip, or with means associated therewith. According to an alternative embodiment, the means in association with the inside surface of the tip protrude into the cylindrical space of the end part, and are brought there in contact with the removal means.

30

The method according to the invention is especially suitable for the removal of such replaceable tips which are attached onto the tip of the end part of the body of

the suction device most preferably with a friction joint. For the removal according to the invention, such replaceable tips for attachment onto the tip of the end part of the body of the suction device are advantageous, in which the inside diameter of the sample space of the replaceable tip tapers from the point of attachment

5 towards the other end of the replaceable tip. In these cases the removal means can in its position for removal, according to one embodiment, be brought into direct contact with the inside surface of the sample space of the replaceable tip. Further the method according to the invention is preferably suitable for the removal of such replaceable tips for attachment onto the tip of the end part of the body of the

10 suction device, which in that end which is intended to be attached to the body of the suction device, or in its vicinity, on the inside surface of the replaceable tip are provided with projections, pegs, fins, circular projections, transversal ribs or other similar means or means within the sample space of the replaceable tip, over which the removal means comes into contact with the replaceable tip in its posi-

15 tion for removal. In this case the removal means comes preferably into contact with only such surfaces which have not been in contact with the sample. When the removal means comes into contact with the inside surface of the replaceable tip, with means projecting into the sample space or with means within the sample space, the movement of the removal means is communicated to the replaceable tip

20 and when the movement is substantially parallel with the longitudinal axis of the replaceable tip, the replaceable tip is made to detach from the end part of the suction device.

25 The movement of the removal means can be brought about by the movement of the piston provided for changing the volume of the cylindrical space of the end part of the body of the suction device, whereby preferably the end of the said piston is brought into contact with the removal means. In moving past its position for blowout, the piston pushes the removal means out of the end part of the body of the suction device and the removal means brings about the detachment of the

30 replaceable tip. According to an alternative embodiment, the movement of the said removal means is brought about by an extension part of the piston, e.g. a part

which is telescopically moveable with regard to the piston, whereby there is no need to move the piston itself past the sample handling positions.

According to a preferred embodiment, after the removal of the replaceable tip, the
5 removal means is returned to its home position by a compression spring arranged in the cylindrical space of the end part of the suction device.

The suction device according to the invention in turn is characterized in that a removal means is arranged to move in the cylindrical space of the end part of the
10 suction device at least partially between two extreme positions, namely between an inner home position and an outer removal position. According to a preferred embodiment, in the removal position, the removal means can be brought to extend out of the aperture of the end part, into the sample space of the replaceable tip mountable on the tip of the end part, in order to remove the replaceable tip from
15 the end part. In its inner extreme position, in the home position, the removal means is thus totally or almost totally within the cylindrical space of the end part of the body of the suction device, but in its outer extreme position, in the removal position, it extends outside of the aperture of the end part of the body of the suction device into the sample space of the replaceable tip, mountable on the end
20 part. In this removal position, the removal means comes into contact with the replaceable tip, with the inside surface of its sample space, with shoulders, ribs, fins or other similar means protruding into the sample space, or with other means associated with the inside surface in the sample space, whereby the replaceable tip
is detached from the end part of the body of the suction device when the move-
25 ment of the removal means continues in the direction of the end part of the suction device and out of this end part. According to an alternative embodiment, the removal means is in its every position, thus both in its home position and in its removal position, within the cylindrical space, and is brought in the removal position into cooperation with shoulders, or other corresponding means associated with
30 the inside surface of the tip and protruding into the cylindrical space.

In a preferred embodiment of the suction device according to the invention, a compression spring is arranged in the cylindrical space of the end part of the suction device between this end part and the removal means in order to return the removal means back to its home position after the removal of the replaceable tip.

- 5 When the removal means is in its removal position, the spring is compressed and it is uncompressed in the home position for the removal means.

- According to an embodiment of the suction device, the removal means and the piston, more specifically that end of the piston which is nearest to the removal means, have at least two positions with respect to each other, in one of which the piston in the sample handling position is not in contact with the removal means, in its home position, and in the second position, which compared to the first one is a rotated position with regard to the longitudinal axis of the piston, the piston at least in some sample handling positions can be brought into contact with the removal means in its home position. This is brought about by suitable mutual designs of the piston and the removal means e.g. so, that the piston and the removal means in the first of the said mutual positions are nested or intermeshed without being in contact with each other and in the latter of the mutual positions they are in contact with each other. In this latter mutual position, the movement of the piston brings the removal means to its removal position in some of the sample handling positions.

- Still according to one embodiment there is provided a spring or spring-like means between the said piston and the removal means in the cylindrical space, which spring or spring-like means in the home position of the removal means is compressed and in the removal position of the removal means is released or uncompressed. The spring locks to its compressed state e.g. when attaching the replaceable tip to the end part of the body of the suction device, whereby at the same time the removal means is brought to its home position. The said spring is preferably designed so that it due to the locked state can remain compressed until an outside contact releases the locked state. The release of the locked state is brought about by the said piston or a telescopically movable extension part thereof

contacting the spring. When the locked state of the spring is released, the spring, when released, brings the removal means to move to the removal position, whereby the replaceable tip is detached from the end part of the suction device. In a preferred embodiment according to the invention the said spring can be a part of the removal means.

According to one embodiment of the invention, the removal means can also be designed so, that it is a separate, as such easily removable supplementary part, which can be removed from the end part of the suction device. This is necessary in those cases, where a possible carryover of samples or reagents by the removal means to the next replaceable tip to be used must be avoided. The removal means can be removed either at the same time with the replaceable tip or after the removal of the replaceable tip either manually or with the movement of the said piston.

In all of the embodiments of the suction device according to the invention the removal means or respectively the shoulders or similar means protruding into the cylindrical space from the inside surface of the tip, are shaped so, that they allow a gas passage to be formed between the cylindrical space and the sample space of the tip. This can be realized e.g. by means of holes, channels, grooves or other similar openings through the removal means.

According to an alternative embodiment of the invention, the suction device does not have a separate removal means, but the piston moving in the cylindrical space for changing the cylindrical volume, or a part thereof, e.g. an extension part telescopically movable with respect to the piston, acts as the said removal means. The removal movement of the tip is brought about by moving the piston past its blow-out position to its removal position, or alternatively by activating the extension part to move into the removal position, into cooperation with the tip as described above. In order to avoid contaminations in this case it is important that the piston or its extension part comes into contact with only such surfaces which have not been in contact with the samples. This embodiment is advantageous especially in

such an embodiment, in which the removal means in each of its positions moves inside the cylindrical space and in which the means associated with the inside surface of the replaceable tip, such as projections, or other similar means, in turn protrude into the cylindrical space.

5

The invention is described in following by means of examples with reference to the enclosed drawings, in which

Fig. 1 illustrates a longitudinal section of a suction device having a removal
10 means and a exchangeable replaceable tip,

Fig. 2 illustrates a section corresponding to Fig. 1 showing the removal of the replaceable tip by means of the removal means,

15 Fig. 3 illustrates the replaceable tip with projections protruding into the sample space,

Figs. 4 and 5 illustrate the alternative embodiments of the removal means, and

20 Fig. 6 illustrates a longitudinal section of such a suction device having a spring-like means between the piston and the removal means.

In the Figs. 1-6 the same reference numbers are used for parts corresponding to each other. In Fig. 1 the end part of the suction device is referenced with number
25 1, the replaceable tip adapted onto the end part with number 2, its sample space with number 10 and the removal means with number 4. In the cylindrical air space 8 of the end part the piston 5 moves slidingly for changing the volume of the cylindrical space 8. In the illustrated embodiment the position 6a of the piston 5 is the home position of the piston and the position 6b is the home position of the removal means 4. The spring 7, which is mounted in the cylindrical space 8
30 between the distal end of the end part 1 of the suction device and the removal means, holds the removal means 4 in its home position 6b. In its home position 6a

the piston 5 is not in contact with the removal means 4 in its home position 6b. When the replaceable tip 2 is to be detached, the piston 5 is brought to move past its home position 6a, whereby the piston 5 first comes into contact with the removal means 4, and the movement continuing, the piston 5 pushes the removal means 4 and when this has come into contact with the inside surface of the replaceable tip 2 or with shoulders, projections or with means in the sample space 10 of the replaceable tip 2, it detaches the replaceable tip 2 from the end part 1 of the suction device. When the replaceable tip 2 is detached, the piston 5 is brought to move back to its home position 6a. The compression spring 7 returns the removal means 4 to its home position 6b.

In Fig. 2 is illustrated the removal according to the invention of the replaceable tip 2 from the end part 1 of the body of the suction device with the removal means 4 being in its removal position 6c. The figure also shows the aperture 9, which forms the gas passage between the sample space 10 of the replaceable tip 2 and the cylindrical space 8.

In Fig. 3 is illustrated an embodiment of the replaceable tip 2 having a shoulder 3, protruding into the sample space 10, which in cooperation with the removal means 4 brings the replaceable tip 2 to be detached in the position 6c of the removal means 4.

In Fig. 4 is illustrated an embodiment of the removal means 4 according to the invention, in which the removal means 4 remains in its home position 6b by means of friction between the means 4 and the wall of the cylindrical space 8, the friction, however, not preventing the movement of the removal means 4. The removal means 4 is made of an elastic material, e.g. of plastic having suitable characteristics. That part of the removal means 4 which extends into the cylindrical space 8 is, in a preferred embodiment, comprised of strips the ends of which extending into the cylindrical space 8 being formed as tips so that the removal means 4 can easily be pushed through the aperture 9 into the cylindrical space 8. The tips lean against the inner walls of the cylindrical space 8 and hold the

removal means 4 slidably attached to the cylindrical space 8. Due to the strip-like construction of the removal means a gas passage is formed between the cylindrical space 8 and the sample space 10 of the replaceable tip 2.

5 Fig. 5 illustrates such a device according to the invention, in which the removal means 4 in the example is formed so that the part of the removal means 4 which extends into the cylindrical part comprises both of longer strips 4b and of shorter strips 4c. The removal means can be made of an elastic material, e.g. of plastic. The ends of the strips 4b and 4c are formed into tips so that the removal means 4
10 can easily be pushed through the aperture 9 into the cylindrical space 8. The tips lean against the inner walls of the cylindrical space 8 and hold the removal means 4 slidably attached in the cylindrical space 8. The end of the piston 5 is respectively designed in a steplike fashion so that the piston in its home position 6a is in such a position with regard to the removal means 4 that the end of the piston 5 is
15 not in contact with the shorter strips 4c of the removal means 4 in the home position 6b of the removal means. When the piston 5 is brought sufficiently further into the cylindrical space 8 with respect to its home position 6a and after that it has been rotated around its longitudinal axis e.g. 180°, when moving back towards its home position 6a and possibly past it, it comes into contact with the longer
20 strips 4b of the removal means 4, whereby a continuation of the movement brings the removal means 4 to move into the removal position and the detachment of the replaceable tip 2.

----- In Fig. 6 there is illustrated a preferred embodiment of the invention, in which
25 there is a spring-like means 11 arranged in the suction device in the cylindrical space between the piston 5 and the removal means 4. This spring-like means 11 has such a construction that it can be compressed and locked into this compressed state. The locked state can be released by an external contact, whereby the means 11 returns to its uncompressed state, in which state the length of the means 11 is
30 substantially greater than the compressed length. This spring-like means 11 is illustrated in the figure locked in its compressed state, whereby the removal means is in its home position 6b. When the piston 5, after having moved past also its

11

blowout position, comes into contact with the means 11, the locked state of the spring means 11 is released and the means 11, when being released to its uncompressed state, causes the removal means 4 to move to the removal position and the detachment of the replaceable tip 2.

5

In all embodiments the removal means 4 is designed so that it allows a gas passage to be formed between the cylindrical space 8 and the sample space 10 of the replaceable tip 2, e.g. by means of holes, channels formed in the removal means 4 and/or in its end 4a nearest the replaceable tip 2, or by means of other similar

10

openings or grooves provided through the removal means.

Claims

1. A method for removing a replaceable tip (2), enclosing a sample space, for use in a suction device for dispensing, transferring, diluting, titrating, or mixing a liquid, having an end part and a cylindrical space therein, **characterized** in that the tip (2) is removed by bringing a removal means (4), mounted in an air space formed jointly by the sample space of the replaceable tip and the cylindrical space (8) of the end part (1) of the suction device, which removal means is movable between its two extreme positions, namely an inner home position (6b) and an outer removal position (6c), to move into cooperation with an inside surface of the replaceable tip (2) mounted on the end part (1), whereby the movement of the removal means (4) into its removal position (6c) brings about the detachment of the replaceable tip (2) from the end part (1).
2. The method according to claim 1, **characterized** in that the said removal means (4) is brought in contact with the inside surface of the tip (2), or in contact with projections, pegs, ribs, or similar means (3) associated with the inside surface, or in contact with a means within the air space engaging the inside surface of the tip (2).
3. The method according to claim 1, **characterized** in that the movement of the removal means (4) to its removal position (6c) is brought about by the movement of a piston (5) moving reciprocatingly in the cylindrical space of the end part of the suction device and provided for changing the volume of the cylindrical space (8).
4. The method according to claim 3, **characterized** in that the end of the piston (5) is brought into contact with the removal means (4).
5. The method according to anyone of claims 1-4, **characterized** in that the removal means (4) is returned to its home position (6b) by means of a compression spring (7).

6. The method according to anyone of claims 1-4, **characterized** in that the removal means (4) is removed by means of the movement of the piston (5) provided for changing the volume of the cylindrical space (8).

5 7. The method according to anyone of claims 1-4 or 6, **characterized** in that the removal means (4) is removed together with the detachable replaceable tip (2).

8. A suction device for dispensing, transferring, diluting, titrating, or mixing a liquid having an end part (1) enclosing a cylindrical space (8) having a reciprocating piston (5) for changing the volume of the cylindrical space (8), the end part (1) being provided with an aperture (9) in an extremity thereof intended for receiving a replaceable tip (2) with a sample space in order to form a gas passage between the sample space (10) of the said replaceable tip (2) and the cylindrical space (8) of the suction device, and provided with means (4) for removing the replaceable tip (2), **characterized** in that the said removal means (4) is arranged to move at least partially in the cylindrical space (8) of the end part (1) of the suction device between two extreme positions, namely between an inner home position (6b) and an outer removal position (6c).

20 9. The suction device according to claim 8, **characterized** in that the removal means (4) is arranged in its removal position (6c) to extend out of the aperture (9) of the end part (1) into the sample space (10) of the replaceable tip (2) attachable onto the end of the end part (1) for removing the replaceable tip (2) from the end part (1).

25

10. The suction device according to claim 8 or 9, **characterized** in that the piston (5) is provided with an telescopically movable extension for moving the removal means (4) to its removal position (6c).

30 11. The suction device according to anyone of the claims 8-10, **characterized** in that the end part (1) is provided with a compression spring (7) for returning the removal means (4) to its home position (6b).

12. The suction device according to anyone of claims 8-10, **characterized** in that the piston (5) and the removal means (4) have in the direction of their common longitudinal axis at least two positions with respect to each other, in one of which the piston (5) and the removal means (4) are at a distance from each other in all
5 of the sample handling positions, and in one of which the piston (5) at least in one of the sample handling positions can be brought into contact with the removal means (4).

13. The suction device according to anyone of claims 8-10, **characterized** in that
10 the cylindrical space (8) of the suction device between the removal means (4) and the piston (5) is provided with a compressible spring means (11), which when being compressed, the removal means (4) is in its home position (6b) and which when being uncompressed, the removal means (4) is in its removal position (6c).

14. The suction device according to anyone of claims 8-10 or 13, **characterized**
15 in that the end of the removal means (4) extending into the cylindrical space (8) comprises a compressible spring-like part, which is compressed, when the removal means (4) is in its home position (6a) and which is uncompressed, when the removal means is in its removal position (6c).

15. The suction device according to anyone of claims 8-14, **characterized** in that the said removal means (4) and/or its end (4a) nearest to the tip (2) is provided with means for forming a gas passage between the sample space (10) of the tip (2)
20 and the cylindrical-space-(8) of the suction device.

16. A suction device for dispensing, transferring, diluting, titrating, or mixing a liquid having an end part (1) enclosing a cylindrical space (8) having a reciprocating piston (5) for changing the volume of the cylindrical space (8), the end part (1) being provided with an aperture (9), in an extremity thereof intended for
25 receiving a replaceable tip (2), in order to form a gas passage between the sample space (10) of the said tip (2) and the cylindrical space (8) of the suction device, **characterized** in that the said piston (5) is adapted to act as a means for removing
30

the tip and is arranged to move at least partially in the cylindrical space (8) of the end part (1) of the suction device between two extreme positions, namely between an inner sampling position and an outer removal position (6c).

- 5 17. The suction device according to claim 16, **characterized** in that the means for removal of the tip comprises an extension part of the piston telescopically movable with regard to the piston.

- * Special categories of cited documents:
- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed
- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
- "&" document member of the same patent family

Date of the actual completion of the international search
4 October 1999

Date of mailing of the international search report
05 -10- 1999

Name and mailing address of the ISA/
Swedish Patent Office
Box 5055, S-102 42 STOCKHOLM

INTERNATIONAL SEARCH REPORT

International application No.
FI99/00499

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

See extra sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/FI99/00499

I. Claims 8-15 relate to a suction device comprising a reciprocating piston and a tip removal means.

II. Claims 16-17 relate to a suction device comprising a reciprocating piston.

The special technical feature in claim 8 is a removal means co-operating with a reciprocating piston for removing the tip. The special technical feature in claim 16 is a reciprocating piston adapted to act as means for removing a tip. These inventions are not so linked as to form a general inventive concept.
